

ROM Kernel Manual Volume 2

Appendix A

Routine Summaries

This appendix contains Unix-like summaries for the routines that are built into the Amiga ROM (or kickstart) software, as well as summaries of routines in disk-loadable libraries. The debug library documentation is included here as well.

These documentation files are organized on a functional basis. For example, things pertinent to Exec are listed under "exec.library/someDocFile". Things pertinent to graphics are listed under "graphics.library/someDocFile".

The tutorial sections of this manual give you information that shows how these routines relate to each other and the prerequisites for calling them.

Most routines are listed as part of a library of routines. Before you can use a routine within your program, you must assure that the library is opened. This is explained fully in the "Libraries" chapter of this manual but it bears repeating here. You open a library by using the **OpenLibrary()** function. The call takes the form:

```
struct LibBase *LibBase;
LibBase = OpenLibrary("library.name", version):
```

where:

library.name

is a string that describes the name of the library you wish to open.

version

is the version number of the library that you wish to have opened. A value of 0 says give me any version. A value of 31, for example (latest as of this writing) says open specifically version 31 of this library or greater if 31 is not available.

If the library is disk-resident, it gets loaded and initialized. The **OpenLibrary()** returns the address of the library base, which you must assign to a specific variable. It is through this means that your program links into the library-specific interface code that is contained in amiga.lib.

The following is a list of the names of the libraries that are currently part of the Amiga software and the corresponding names of the library base pointers associated with them:

| Library Name | Library Base Pointer Name |
|--------------|---------------------------|
| | |

exec.library ExecBase clist.library ClistBase graphics.library **GfxBase** layers.library LaversBase intuition.library **IntuitionBase** Math Base mathffp.library mathtrans.library MathTransBase mathieeedoubbas.library MathleeeDoubBasBase dos.library DosBase translator.library TranslatorBase icon.library **IconBase**

diskfont.library DiskfontBase

ramlib.library

(not useful to C language)

Example:

```
#include "graphics/gfx.h"
struct GfxBase *GfxBase;
GfxBase = OpenLibrary("graphics.library",0);
if(GfxBase == NULL) exit(NO_GRAPHICS_LIBRARY_FOUND);
```

Note:

If your program is coming up through the normal startup code (see the Workbench chapter of this manual) the exec.library and dos.library are already opened for you. Thus you needn't open them yourself.

The reason for this code are

1. C, when calling a routine, takes the parameters for the routine and pushes them. onto the stack. For example:

```
x = Routine(parmA, parmB);
```

Then it calls a routine named "_Routine" (adds an underscore to the head of the routine name).

2. The underlying ROM (or disk based) code usually expects its parameters to be passed in registers rather than on the stack. This is to make it truely general purpose (does not impose a particular stack frame), and more efficient for assembly language coding.

Therefore, the interface code at _Routine, in turn, saves the contents of registers the routine will use and pulls parameters off of the stack and jams them into registers, finally passing control directly to the actual starting location of the routine itself.

The linker needs the library base location since it is through a jump-with-offset from a machine register that the _Routine entry point is found. (The Amiga uses a relocating loader in AmigaDOS, so you can never be sure exactly where a library of routines is located. However once the system has loaded a library, it knows how and where to find it and gives you a way to use the library's routines.)

The following shows typical interface code linked to your program from amiga.lib:

```
xref _LibBase
                              ;Library base name is defined in
                              ;user's file, this code gets linked
                              ;to user's program, get the value
                              from there when library is opened.
           xdef _Routine
                              ;make _Routine name external,
                              ; visible to linker.
_Routine:
           move.l
                      A6,-(sp)
                                         ;save register(s)
           move.l
                      8(sp),A0/A1
                                         copy parms A and B to regs.
           move.l
                      _LibBase,A6
                                         ; load library base address
           isr
                      _LVORoutine(A6);go to real routine
           move.l
                      (sp)+,A6
                                         restore registers;
           rts
```

where _LVORoutine is a value representing the offset, within the library, at which the "real" routine (the one that expects parameters in registers) is located.

When you are finished using a library, at the end of your program, you should close it, using the CloseLibrary function as follows:

CloseLibrary(LibBase);

If the system is running out of memory and needs to free up space, it can check the library-accessors field for various libraries and for those whose accessors value is zero, it can retrieve the memory that the library had used.

RESULTS error

-The word to add to the beginning of the character list

The clist header used to manage this character list, as returned by AllocList or StrToCL.

INPUTS cList -

word

FUNCTION
Add a word to the beginning of the character list described by the clist.

non-zero indicates the number of bytes not added.

Partial words are not added, so error is always zero or two.

clist.llbrary/UnGetCLMord

UnCetCLMord - add a word to the beginning of a character list

diskfont.library/AvailFonts buffer indicates that it exists as an entry in a font contents file -- the underlying font file has not been if non-zero, this indicates the number of bytes needed for AvailFonts in addition to those supplied. Thus structure elements were not returned because of types - AFE_MEMORY is set to search memory for fonts to fill-the structure, AFE_DISK is set to search the disk for fonts to fill the structure. Both can be specified. AvailFonts elements, There will be duplicate entries for fonts found both in memory and on disk, differing only by type. The existance of a disk font in the AvailFonts - build an array of all fonts in memory / on disk via OpenDiskFont, those already in memory are accessed via OpenFont. The TextAttr structure required by the open calls is part of the information AvailFonts supplies. checked for validity, thus an OpenDiskFont of it may buffer - filled with struct AvailFontsHeader followed by the AvailFonts fills a user supplied buffer with the structure, described below, that contains information about all the fonts available in memory and/or on disk. Those fonts available on disk need to be loaded into memory and opened buffer - memory to be filled with struct AvailFontsHeader followed by an array of AvailFonts elements, which contains entries for the available fonts and their bufBytes - the number of bytes in the buffer Dec 3 17:04 1985 diskfont.doc Page 2 insufficient bufbytes. diskfont.library/AvailFonts fa11. error FUNCTION RESULTS Dec 3 17:04 1985 diskfont.doc Page 1 diskfont.library/AvailFonts

diskfont.library/OpenDiskFont

diskfont.library/OpenDiskFont

OpenDiskFont - load and get a pointer to a disk font.

SYNOPSIS

Z

font = OpenDiskFont(textAttr)
D0 2

FUNCTION

This function finds the font with the specified textAttr on disk, loads it into memory, and returns a pointer to the font that can be used in subsequent SetFont and CloseFont calls. It is important to match this call with a corresponding CloseFont call for effective management of font memory.

If the font is already in memory, the copy in memory is used. The disk copy is not reloaded.

INPUTS

textAttr - a TextAttr structure that describes the text font attributes desired.

EXCEPTIONS

DO is zero if the desired font cannot be found.

Exec/AddTask This function will temporarily use space from the new task's stack for the task's initial set of registers. This space is allocated starting at the SPREG location specified in the task control block (not from SPUPPER). This means that a task stack may contain static data put there prior to its execution. This is useful for providing initialized global variables or some tasks may want to use this space for passing the task its initial arguments. Certain fields of the task control block must be initialized and a minimal stack should be allocated prior to calling this function. AddTask -- add a task to the system AddTask(task, initialPC, finalPC) Al A2 A3 Add a task to the system. 'AddTask NOPSIS NCTION 빛

4 09:33 1985 exec.doc Page 10

A task's initial registers are set to zero (except the PC). zero, the system will use a general finalizer. This pointer is placed on the stack as if it were the outermost return address. task - pointer to the task control block initialPC - the initial entry point finalPC - the finalization code entry point. If

| NAME Allocate allocate a block of memory | NAME AllocEntry allocate many regions of memory |
| SYNOPSIS memoryBlock = allocate(freeList, byteSize) D0 D0 A0 | SYNOPSIS memList = AllocEntry (memList) D0 A0 |
| FUNCTION This function is used to allocate blocks of memory from a given free memory pool. It will return the first free block that is greater than or equal to the requested size. | FUNCTION This routine takes a memList structure and allocates enough memory to hold the required memory as well as a MemList structure to keep track of it. These MemList structures may be linked together in a task control block to keep |
| All blocks, whether free or allocated, will be block aligned; hence, all allocation sizes are rounded up to the next block even value (e.g. the minimum allocation resolution is 8 bytes). | track of the total memory usage of this task. INPUTS memList A memList structure filled in with memEntry structures. |
| This function, when used in conjunction with a private free list, can be used to manage an application's internal data memory. | RESULIS memList A different memList filled in with the actual memory allocated, and their sizes. If enough memory cannot be obtained, then the |
| IMPUTS freeList - points to the memory list header byteSize - the size of the desired block in bytes | requirements of the falled allocation are returned and bit 31 is set. EXAMPLES |
| RESULI memoryBlock - a pointer to the just allocated free block. If there are no free regions large enough to satisfy the request, return zero. If the amount of requested memory is invalid, return zero. | The user wants five regions of 2, 4, 8, 16, and 32 bytes in size with requirements of MEME_CIEAR, MEME_PUBLIC, MEME_CHIP.OR.MEME_CIEAR, MEME_FAST.OR.MEME_CIEAR, and MEME_PUBLIC.OR.MEME_CIEAR respectively. The following code fragment would do that: |

| Dec 4 09:33 1985 exec.doc Page 14 Exec/AllocMem NAVE AllocMem allocate memory given certain requirements SYNOPSIS memoryBlock = AllocMem(byteSize, requirements) D0 D1-0:31 FUNCTION This is the memory allocator to be used by system code and applications. It provides a means of specifying whether the allocation should be made in a memory area accessible to the chips, or accessible to shared system code that needs to be compatibable with memory mapped systems. Memory is allocated based on the "requirements" listed. The rule is that (requirements & attributes) == requirements for any particular memory block. | with the requested attributes and room for the memory request. INPUTS byteSize - the size of the desired block in bytes This number is rounded up to the next larger block size for the actual allocation. requirements - (still in flux) (see IA_Structs for bit definitions) MEMB_PUBLIC: memory must not be mapped, swapped, or otherwise made non-addressable. ALL MEMORY THAT IS REFERENCED VIA INTERRUPTS AND/OR BY OTHER TASKS MUST BE EITHER PUBLIC OR LOCKED INTO MEMORY! This includes both code and data. | MEMB_CHIP: Only certain parts of memory are reachable by the special chip sets' DWA circuitry. Anything that will use on-chip DWA must be in memory with this attribute. DWA includes screen memory, things that are blitted, audio blocks, raw disc buffers, etc. MEMB_FAST: This is non-chip memory. It is possible for the processor to get locked out of chip memory under certain conditions. If one cannot accept these delays, then one should use FAST memory (by default the system will allocate from FAST memory first anyway). |

| Exec/AllocSignal |
| NAME AllocSignal allocate a signal bit |
| SYNOPSIS signalNum = AllocSignal(signalNum) D0 |
| FUNCTION Allocate a signal bit from the current tasks pool. Either a particular bit, or the next free bit may be allocated. The signal associated with the newly allocated bit will be properly initialized (cleared). |
| If the signal is already in use (or no free signals are available) a -1 is returned. |
| This function can only be used by the currently running task. |
| WARNING Signals may not be allocated or freed from exception handling code. |
| INPUTS signalNum - the desired signal number {of 031} or -1 for no preference. |
| RESULTS signalNum - the signal bit number allocated {031}. If no signals are available, this function returns -1. |
| SEE ALSO FreeSignal |
| |
| |
| |

The mamory will be initialized to all zeros.

MEMB_CLEAR:

RESULT

Dec 4 09:33 1985 exec.doc Page 15

memoryBlock - a pointer to the allocated free block.

If there are no free regions large enough to satisfy the request (or if the amount of requested memory is invalid), return zero.

EXAMELES
AllocHem(321, MEMB_CHIP) - private chip memory
AllocHem(25, MEMB_FUBLIC) - a "public" system structure that
does not require chip memory.

EXCEPTIONS
If the free list is corrupt, the system will panic.

| Exec/ColdReset | Exec/Deallocate Exec/Deallocate |
| NAME ColdReset cause a system coldstart to occur | NAME Deallocate deallocate a block of memory |
| SYNOPSIS ColdReset() | SYNOPSIS Deallocate(freeList, memoryBlock, byteSize) |
| FUNCTION This function causes a coldstart system reset sequence identical to that which occurs at power-on. All current system activities will be stopped, and the entire software system will be re-initialized. Nothing will be preserved. This function will assert processor RESET to reset all hardware devices. | FUNCTION FUNCTION This function deallocates memory by returning it to the appropriate free memory pool. This function can be used to free an entire block allocated with the above function, or it can be used to free a sub-block of a previously allocated block. |
| EXCEPTION This function operates in supervisor mode only. Any attempt to perform this function from user mode will result in a privilege violation trap. | If memoryBlock is not on a block boundary (MEM_BLOCKSIZE) then it will be rounded down. Note that this will work correctly with all the memory allocation routines, but may cause surprises if one is freeing only part of a region. If byteSize is null, nothing happens. Also, the size of the block will be rounded up, so the freed block will fill an entire memory block. |
| | INPUTS freeList - points to the free list memoryBlock - memory block to return byteSize - the size of the desired block in bytes |

Exec/FindName

NAME

SYNOPSIS
node = FindName(start, name)
D0 A1

FUNCTION

Traverse a system list until a node with the given name is found. To find multiple occurances of a string, this function may be called with a node starting point.

start - a list header or a list node to start the search (if node, this one is skipped)
name - a pointer to a name string terminated with null

node - a pointer to the node with the same name else zero to indicate that the string was not found.

RESULTS

Exec/MakeLibrary

Exec/MakeL1brary

SEE

MakeLibrary -- construct a library

SYNOPSIS

8

FUNCTION

This function is used for constructing a library vector and data area. Space for the library is allocated from the system's free memory pool. The size fields of the library are filled. The data portion of the library is initialized. A library specific entrypoint is called (init) if present.

INPUTS

- pointer to an array of function pointers or function displacements. If the first word of the array is -1, then the array contains relative word displacements (based off of vectors); otherwise, the array contains absolute function pointers. Vectors

structure - points to an "InitStruct" data region. If null, then it will not be called.

the library to the system. If null, it will not be called. When it is called, it will be called with the libAddr in D0, and its result will be the result an entry point that will be called before adding of this function. init

the size of the library data area, including the standard library node data. dSize -

 pointer to a memory segment list (used by DOS)
 This is passed to a library's init code. segilist

RESULT

library - the reference address of the library. This is the address used in references to the library, not the beginning of the memory area allocated.

EXCEPTION

If the library vector table require more system memory than is available, this function will cause a system panic.

| Dec 4 09:33 1985 exec.doc Pac Exec/SandIO | NAME SendIO initiate an I/O command | SYNOPSIS SendIO(10Request) A1 | FUNCTION This function requests command specified in the will return regardless | INPUTS 10Request - pointer to an I/O request | SEE ALSO Dolo, Waltio | | | · | | |

Exec/ReplyMsg

NAME ReplyMsg -- put a message to its reply port

Exec/Replyffsg

SYNOPSIS ReplyMsg (message) Al

FUNCTION

Dec 4 09:33 1985 exec.doc Page 53

This function sends a message to its reply port. This is usually done when the receiver of a message has finished and wants to return it to the sender (so that it can be re-used or deallocated, whatever).

message - a pointer to the message

IMPGF

| Exec/SetExcept | , signalMask) D1 E2 D2 D3 D3 D4 D4 D5 D5 D6 D6 D6 D6 D7 | he signals specified in be effected | otion signals: | | |
|--|--|---|---|----------------------------|--|
| Dec 4 09:33 1985 exec.doc Page 55 Exec/SetExcept NAME SetExcept define certain signals to cause exceptions | oldSignals = SetExcept (newSignals, signalMask) D0 D1 FUNCTION This function defines which of the task's signals will cause an exception. When any of the signals occurs the task's exception handler will be dispatched. If the signal occurred prior to calling SetExcept, the exception will happen immediately. | INPUTS newSignals - the new values for the signals specified in signalMask. signalMask - the set of signals to be effected RESULTS oldSignals - the prior exception signals | EXAMPLE Get the current state of all exception signals: SetExcept(0,0) Change a few exception signals: SetExcept(\$1374,\$1074) | SEE ALSO Signal, SetSignal | |

Exac/SatFunction Setfunction is a functional way of changing those parts of a library that are checksummed. They are changed in such a way that the summing process will never falsely declare a library to be invalid. funcOffset - the offset that FuncEntry should be put at. SYNOPSIS
oldFunc = SetFunction(library, funcOffset, funcEntry)
D0 A1 A0.W D0 SetFunction -- change a function vector in a library INPUTS library - a pointer to the library to be changed Exec/SetFunction FUNCTION MARE

Dec 4 09:33 1985 exec.doc Page 56

funcEntry - pointer to new function

| Dec 4 09:33 1985 exec.doc Page 58 | Exec/SetSlgnal E | NAME SetSignal define the state of this task's signals | SYNOPSIS oldSignals = SetSignal (newSignals, signalMask) D0 D1 | FUNCTION This function defines the states of the task's signals. This function is considered dangerous. IMPUTS newSignals - the new values for the signals specified in signalMask - the set of signals to be effected RESULTS oldSignals - the prior values for all signals EXAMPLE Get the current state of all signals: SetSignal(0,0) Clear all signals: SetSignal(0,0) SEE ALSO Signal, Wait | |
|-----------------------------------|-------------------|---|---|--|--|
| Dec 4 09:33 1985 exec.doc Page 57 | Exec/SetIntVector | NAME SetIntVector set a system interrupt vector | SYNOPSIS oldInterrupt = SetIntVector(intNumber, interrupt) D0 D1 D1 D2 D2 D2 D3 | FUNCTION This function provides a mechanism for setting the system interrupt vectors. Both the code and data pointers of the vector are set to the new values. A pointer to the old interrupt structure is returned. When the system calls the spacified interrupt code the registers are setup as follows: Do - scratch Do - scratch (on entry: active portia interrupts) Ao - scratch (on entry: pointer to chiphase) Ai - scratch (on entry: interrupt's data segment) Ai - scratch (on entry: interrupt on call) Ai - scratch (on entry: interrupt but number (014) Interrupt - a pointer to a node structure confaining the handler's entry point and data segment pointer: It is a good idea to give the node a name so that other users may identify who currently has control of the interrupt. RESULT A pointer to the prior interrupt node which had control of this interrupt. | |

| NAME SuperState enter supervisor state with user stack | ate return to user state with user stack |
| SYNOPSIS oldSymStack = SuperState() D0 | SYNOPSIS UserState (sysStack) D0 |
| EUNCTION Enter supervisor mode while running on the user's stack. The user still has access to user stack variables. Be careful though, the user stack must be large enough to accommodate space for all interrupt data this includes all possible nesting of interrupts. This function is a no op when called from supervisor state. RESULTS oldsysStack - system stack pointer Save this. It will come in useful when you return to user state. If the system is already in supervisor mode, oldsysStack is zero. | FUNCTION Return to user state with user stack, from supervisor state with user stack. This function is normally used in conjunction with the SuperState function above. This function must not be called from the user state. INPUT SysStack - supervisor stack pointer SEE ALSO SuperState |
| User State User State | |

NAME
AddFont -- add a font to the system list

graphics.library/AddFont

SYNOPSIS
AddFont (textFont), GraphicsLib
Al A6

Dec 3 17:05 1985 graphics.doc Page 5

FUNCTION

This function adds the text font to the system, making it available for use by any application. The font added must be in public memory, and remain until successfully removed.

INPUIS textFont structure in public ram.

graphics.library/Allockaster

Allockaster -- allocate space for a Bit Plane

SYNOPSIS
AllocRaster (width, height)
d0 d1

Dec 3 17:05 1985 graphics.doc Page 7

graphics.library/Allockaster

FUNCTION
This function calls the memory allocation routines
to allocate memory space for a bitplane width bits
wide and height bits high.

Returns a pointer to the first word if successful. Return 0 if unable to allocate that amount of space.

INPUTS
rastPort - the RastPort from which the text attributes are
extracted.
textAttr - the TextAttr structure to be filled.

FUNCTION
This function fills the text attributes structure with the attributes of the current font in the rastPort.

NAME
AskFont - get the text attributes of the current font

graphics.library/Askfont

Dec 3 17:05 1985 graphics.doc Page 13

SYNOPSIS Asidfont (rastPort, textAttr), graphicsLib Al A0 A6

Dec 3 17:05 1985 graphics.doc Page 15

graphics.library/BitBitMap

graphics.library/BltBitMap

BitBitMap -- move a rectangle in a raster

A0 D0 D1 A1 DestX, DestY, SizeX, SizeY, Minterm, Mask, TempA); D2 D3 D4 D5 D6 D7 A2 planes = BitBitMap(SrcBitMap, SrcX, SrcY, DestBitMap, Do Ao Ao Do D1 Al Al

perform non-destructive blits to move a rectangle from one

area in a raster to another area, which can be on a different raster.

SrcBitMap, DestBitMap - the BitMap(s) containing the rectangles

 the planes copied from the source to the destination are only those whose plane numbers are identical and less than the minimum plane count and whose write mask is

SrcX, SrcY - the x and y coordinates of the upper left corner of the source rectangle. Valid range is positive signed integer such that the raster word's offset SrcBitMap and DestBitMap can be identical

DestX, DestY - the x and y coordinates of the upper left 0.. (32767-Size)

corner of the destination for the rectangle. Valid range is as for Src.
SizeX, SizeY - the size of the rectangle to be moved. Valid range is (X: 1..976; Y: 1..1023 such that final raster word's offset is 0..32767)

Minterm - the logic function to apply to the rectangle when A is non-zero (i.e. within the rectangle). B is the source rectangle and C, D is the destination for the rectangle.

- \$000 is a vanilla copy - \$030 inverts the source before the copy - \$050 ignores the source and inverts the destination - see the hardware reference manual for other combinations Mask - the write mask to apply to this operation. Bits set indicate the corresponding planes (if not greater than

the minimum plane count) are to participate in the operation. Typically this is set to 0xff.

TempA - If the copy overlaps exactly to the left or right (1.0. the scan line addresses overlap), and TempA is non-zero, it points to enough chip accessable memory to hold a line of A source for the blit.

RESULTS

planes - the number of planes actually involved in the blit.

EXCEPTIONS

Dec 3 17:05 1985 graphics.doc Page 16

This bit is assumed to be friendly: no errors conditions (e.g. a rectangle outside the BitMap bounds) are tested or reported. A plane count that is less than expected can be attributed to a failure to allocate a TempA when it was needed and mull

graphics.library/BltPattern al points to RastPort
a0 points to 2 dimensional mask if needed
x1,y1 upper left of rectangular region in RastPort
maxx.maxy points to lower right of rectangular region in RastPort

Clear a rectangular swath from the current position to the right edge of the rastPort. The height of the swath is taken from that of the current text font, and the vertical positioning of the swath is adjusted by the text baseline, such that text output at this position would lie wholly on this newly cleared area.

Clearing consists of setting the color of the swath to zero, or, if the DrawMode is 2, to the BgPen.

graphics.library/InitGels

NAME InitGels -- initialize a gel list; must be called Before using gels

SYNCPSIS InitGels (head, tail, Ginfo) a0 a1 a2

FUNCTION

Dec 3 17:05 1985 graphics.doc Page 49

graphics.library/InitGels

Assigns the VSprites as the head and tail of the gel list in GfxBase Links these two gels together as the keystones of the list If the collHandler vector points to some memory array, sets the BORDERHIT vector to NULL

graphics.library/InitRastPort Initialize a RastPort structure to standard values The struct Rastport describes a control structure for a write-able raster. The RastPort structure describes how a complete single playfield display will be written into. A RastPort structure is referenced whenever any drawing or filling establish where, in memory, the rasters are located. To do graphics with this RastPort the user must set up the BitMap pointer in the RastPort. The section of memory which is being used in this way may or may not be presently a part of the current actual onscreen display memory. The name of the actual memory section which is linked to the RastPort is referred to here as a "raster" or operations are to be performed on a section of memory. routine InitRastPort only staults. It does NOT DrawMode = JAM2 The font is set to the standard system font InitRastPort - Initialize raster port structure all entries in RastPort get zeroed out. = pointer to a RastPort structure. NAME
SetFont -- set the text font and attributes in a RastPort

STNOPSIS
error = SetFont(rastPort, font), graphicsLib

DO Al AO A6

FUNCTION
This function sets the font in the RastPort to that described
by font, and updates the text attributes to reflect that
change. If TextAttr is zero, this call leaves the RastPort
with no font. This function clears the effect of any previous
soft styles.

INPUTS
RastPort - the RastPort in which the text attributes are
changed.
font - an open font.

.

| Graphics.library/SetECB4 NAME SetECB4 set on SetECB4 (vp. n, a0 D0 INPUTS vp= viewport to a n = the color numb r = red level g = green level g = green level b = blue level in the structure The selected color If the color value BUCS If the color value the next viewport. SEE ALSO LoadRCB4 |

|---|------------|
|---|------------|

RESULTS

style - the new font style to set, subject to enable.
enable - those bits in style to be changed. Any set bits here that would not be set as a result of AskSoftStyle will be ignored, and the newStyle result will not be as expected.

rastPort - the RastPort from which the font and style

are extracted.

INPUTS

style - the resulting style, both as a result of previous soft style selection, the effect of this function, and the style inherent in the set font.

This function alters the soft style of the current font. Only those bits that are also set in enable are affected. The resulting style is returned, since some style request changes will not be honored when the implicit style of the font precludes changing them.

newStyle = SetSoftStyle(rastPort, style, enable), graphicsLib

AddCadget

AdCadget

-- add a Gadget to the Gadget list of the Window or Screen AddCadget

SHORT AddCadget (Pointer, Gadget, Position);

Adds the specified Gadget to the Gadget list of the given Window or Screen, linked in at the position in the list specified by the Position argument (that is, if Pos == 0, the Gadget will be inserted at the head of the list, and if Position == 1 then the Gadget will be inserted after the first Gadget and before the second). If the Position you specify is greater than the number of Gadgets in the list, This procedure returns the position at which your Gadget was added. your Gadget will be added to the end of the list. The SCRCANCET Flag of the Gadget specifies whether the Pointer argument points to a Window (SCRCANCET not set) or a Screen (SCRCANCET is set).

list is to specify a Position of -1. That way, only the 65536th (and multiples of it) will be inserted at the wrong position. The return value of the procedure will tell you where it was A relatively safe way to add the Cadget to the end of the actually inserted. MOTE: The System Window and Screen Cadgets are initially added to the front of the Cadget List. The reason for this is: if you position your own Cadgets in some way that interferes with the graphical representation of the system Cadgets, the system's ones will be "hit" first by User. If you then start adding Cadgets to the front of the list, you will disturb this plan, so beware. On the other hand, if you don't violate the design rule of never overlapping your Cadgets, there's no problem.

Cadget = pointer to the new Cadget
Position = integer position in the list for the new Cadget (starting from
zero as the first position in the list) Pointer = pointer to the Window or Screen to get your Cadget

Returns the position of where the Cadget was actually added.

None

AllocRemember

AllocHem and create a link node to make FreeHem easy AllocRemember

SYNOPSIS

AllocRemember (Remember Key, Size, Elags);

This routine calls the EXEC AllocMem() function for you, but also links the parameters of the allocation into a master list, so that you can simply call the Intuition routine FreeRemember() at a later time to deallocate all allocated memory without being required to remember the details of the memory you've allocated.

This routine will have two primary uses:

Let's say that you're doing a long series of allocations in a procedure (such as the Intuition OpenWindow() procedure). If any one of the allocations falls for lack of memory, you need to abort the procedure. Abandoning ship correctly involves freeling up what memory you've already allocated. This procedure allows you to free up that memory easily, without being required to keep track of how many allocations you already done, what the sizes of the allocations were, where the memory was allocated.

Also, in the more general case, you may do all of the allocations in you entire program using this routine. Then, when your program is exiting, you can free it all up at once with a simple call to FreeRemember().

You create the "anchor" for the allocation master list by creating you call AllocRemember(), the routine actually does two memory allocations, one for the memory you want and the other for a copy of a Remember structure. The Remember structure is filled in with data describing your memory allocation, and it's linked into the master list pointed to by your RememberKey. Then, to a variable that's a pointer to struct Remember, and initializing that pointer to NULL. This is called the RememberKey. Whenever free up any memory that's been allocated, all you have to do is call FreeRemember() with your RememberKey.

As you will see, you Please read the Freekemember() header too. As you will see, yo can select to either free just the link nodes and keep all the allocated memory for yourself, or you can elect to free both the nodes and your memory buffers. See the "Amiga ROM Kernel Manual" for a decsription of the AllocMem() call and the values you should use for the Size and Flags variables.

INPUTS

RememberKay = the address of a pointer to struct Remember. Before the very first call to AllocRemember, initialize this pointer to NULL. For instance:

Dec 3 17:04 1985 intuition.doc Page 5

AllocRemember (GRememberKey, BUFSIZE, MEMF_CHIP); FreeRemember (&Remember Key, TRUE);

Size = the size in bytes of the memory allocation. Please refer to the EXEC Allockem() function in the "Amiga ROM Kernel Manual"

Flags = the specifications for the memory allocation. Please refer to the EXEC AllocMem() function in the "Amiga ROM Kernel Manual" for details. for details

RESULT

address of your requested memory block. Also, the node to your block will be linked into the list pointed to by your RememberKey variable. If the allocation fails, this routine returns NULL and the list pointed to by RememberKey, if any, will be undisturbed. If the memory allocation is successful, this routine returns the byte

AutoRequest

Automatically build and get reponse from a Requester ; AutoRequest

AutoRequest

NA SE

Positive lags, Negative lags, Width, Height); AutoRequest (Window, BodyText, PositiveText, NegativeText,

SYNOPSIS

waits for a response from the user or the system to satisfy your request. If the response is Positive, this procedure returns TRUE. If the response is negative, this procedure returns FALSE. This procedure automatically builds a Requester for you and then

This procedure first preserves the state of the IDGMP values of the Window argument. Then it creates an IDGMPlag specification by merging together your PositiveFlags, NegativeFlags, and the IDGMP class GADGFURP. You may choose to specify no flags for either the Positiveflags or Negativeflags arguments.

your Window pointer and the IDCMP flags. Please refer to BuildSysRequest() for a description of the Intulext that you are It's an important The IntuiText arguments, and the Width and Height values, are passed directly to the BuildSysRequest() procedure along with your Window pointer and the IDCMP flags. Please refer to expected to supply when calling this routine. It's an import: but long-winded description that need not be duplicated here.

If the BuildSysRequest() procedure does not return a pointer to a Window, it will return TRUE or FALSE (not valid structure pointers) instead, and these BOOL values will be returned to you immediately. On the other hand, if a valid Window pointer is returned, that Window will have had its IDCMP Ports and flags initialized according to your specifications. AutoRequest() then waits for an IDCMP message on the UserPort, which message will satisfy one of three requirements: - either the message is of a class that matches

one of your PositiveFlags arguments (if you've supplied any), in which case this routine returns TRUE.

- the message class matches one of your NegativeFlags arguments (if you've supplied any), in which case ò this routine returns FALSE.

the only other possibility is that the IDCMP message is of class CADCETUP, which means that one of the two Gadgets, as specified by the PositiveText and NegativeText arguments, was selected by the user. If the TRUE Cadget was selected, TRUE is returned. If the FALSE Gadget was selected, FALSE is returned.

When the dust has settled, this routine calls FreeSysRequest() if necessary to clean up the Requester and any other allocated memory.

INPUTS

Window = pointer to a Window structure

Dec 3 17:04 1985 intuition.doc Page 8 **Begin**Refresh SYNOPSIS FUNCTION SEE ALSO None None PositiveText = pointer to an IntuiText structure
MegativeText = pointer to an IntuiText structure
PositiveFlags = flags for the IDCMP
MegativeFlags = flags for the IDCMP
Width, Height = the sizes required for the rendering of the Requester complete description of the chain of events that might lead to either of these values being returned. BodyText = pointer to an IntuiText structure Dec 3 17:04 1985 intuition.doc Page 7 BuildSysRequest () SEE ALSO

BeginRefresh For instance, if you have a SIMPLE REFRESH Window which is partially concealed and the user brings it to the front, you will receive a message asking you to refresh your display. If you call BeginRefresh() before doing any of the rendering, then the layer that underlies your Window will be arranged such that the only rendering that will actually After you have performed your refresh of the display, you should call EndRefresh() to reset the state of the layer and the Window. Then you This routine sets up your Window for optimized refreshing. It sets intuition internal states and then sets up the layer underlying your Window for a call to the layer library. There, the "clip rectangles" of the layer are reorganized in a fashion where any rendering performed in your Window (until you call to EndRefresh()) will occur only in the regions which need to be refreshed. The phrase "clip rectangles" refers to the division of your Window into visible and concealed rectangles. message of class REFRESHWINDOW through the IDOMP, or an input event of class IECLASS_REFRESHWINDOW through the Console Device. Whenever you are told that your Window needs refreshing, you should call BeginRefresh() and EndRefresh() to clear the refresh-needed state, even if you don't plan on doing any rendering. You learn that your Window needs refreshing by receiving either a take place will be that which goes to the newly-revealed areas. Window = pointer to the Window structure which needs refreshing For more information about clipping rectangles and the layer library, refer to the "Amiga ROM Kernel Manual". Sets up a Window for optimized refreshing may proceed with rendering to the Window as usual. The "Windows" chapter in this book is very performance-efficient. BeginRefresh (Window); i Beginkefresh EndRefresh()

Dec 3 17:04 1985 intuition.doc Page 9

BuildSysRequest

PulldSysRequest

-- Build and display a system Requester BuildSysRequest

PositiveText, NegativeText, BuildSyaRequest(Window, BodyText, Po IDCPFlags, Width, Height);

which response may include either selecting one of the Cadgets or causing some other event to be noticed by Intuition (like DISKINSERIED, for instance). After the Requester is satisfied, you should call the FreeSyzRequest() procedure to remove the Requester and free up any Wait() on those ports to detect the user's response to your Requester, This procedure builds a Requester based on the supplied information. If all goes well and the Requester is constructed, this procedure returns a pointer to the Window in which the Requester appears. That Window will have the IDCMP UserPort and WindowPort initialized to reflect the flags found in the IDCMPFlags argument. You may then allocated memory. If it isn't possible to construct the Requester for any reason, this procedure will instead use the text arguments to construct a text string for a call to the DisplayAlert() procedure, and then will return either a TRUE or FALSE depending on whether DisplayAlert() returned A FALSE or TRUE respectively.

created by this routine to be bound to a particular Window, you should If the Window argument you supply is equal to NUIL, a new Window will be created for you in the Workbench Screen. If you want the Requester not supply a Window argument of NULL.

The text arguments are used to construct the display. They are pointers to instances of the struct IntuiText.

the Requester. As usual with IntuiText data, you may link several lines of text together, and the text may be placed in various locations in the Requester. This IntuiText pointer will be stored The Bodyfext argument should be used to describe the nature of In the RegText variable of the new Requester

Retry. Good." If the Requester The PositiveText argument describes the text that you want associated with the user choice of "Yes. TRUE. Retry. Good." If the Requester the DisplayAlert() mechanism is used, this text will be rendered in the lower-left of the Requester, which Gadget will have the GadgetID field set to TRUE. If the Requester cannot be opened and is successfully opened, this text will be rendered in a Gadget in pointer can be set to NULL, which specifies that there is no TRUE the lower-left corner of the Alert display with additional text specifying that the left mouse button will select this choice.

Bad." If the Requester The NegativeText argument describes the text that you want associated Cancel. FALSE. with the user choice of "No.

Dec 3 17:04 1985 intuition.doc Page 10

is successfully opened, this text will be rendered in a Gadget in the lower-right of the Requester, which Gadget will have the GadgetID field set to FALSE. If the Requester cannot be opened and the DisplayAlert() mechanism is used, this text will be rendered in pointer cannot be set to NULL. There must always be a way for the the lower-right corner of the Alert display with additional text specifying that the right mouse button will select this choice. to cancel this Requester

The Positive and Negative Gadgets created by this routine have the following features: - BOOLCADCET

- RELVERIFY

- REQCADCET - TOCKLESELECT

of the Cadgets. These include defines like AUTODRAMMODE, AUTOLEFIEDCE, AUTOTOPEDCE and AUTOFRONTPEN. You can find these in your local When defining the text for your Gadgets, you may find it convenient to use the special defines used by Intuition for the construction intuition.h (or intuition.i) file.

The Width and Height values describe the size of the Requester. All of your BodyText must fit within the Width and Height of your Requester. The Gadgets will be created to conform to your sizes.

The primary implication of this will be that the IDCMPFlags and Ports will be disturbed by a call to this routine. To assure upward-compatibility, it's your responsibility to make sure that procedure, a new Window is opened in the same Screen as the one containing your Window. However, with a forthcoming update of Intuition, this will change such that the Requester will be opened in the Window supplied as an argument to this routine, if possible. the Ports and IDCMPFlags of the Window passed to the routine are VERY IMPORTANT NOTE: for the preliminary release of this protected before the call.

IDOMPFlags = the IDOMP flags you want used for the initialization of the PositiveText = pointer to an IntuiText structure NegativeText = pointer to an IntuiText structure BodyText = pointer to an IntuiText structure Window = pointer to a Window structure

IDCMP of the Window containing this Requester Width, Height = the size required to render your Requester

Requester was rendered. If, however, the Requester cannot be rendered in the Window, this routine will have called DisplayAlert() before returning and will pass back TRUE if the user pressed the left mouse button and FALSE if the user pressed the right mouse button. returned by this procedure is a pointer to the Window in which the If the Requester was successfully rendered in a Window, the value

This procedure currently opens a Window as wide as the Screen in

DisplayAlert

-- Create a display of an Alert message DisplayAlert

SYNOPSIS

DisplayAlert (AlertNumber, String, Height);

FUNCTION

Creates an Alert display with the specified message.

If the system can recover from this Alert, its a RECOVERY_ALERT and this routine waits until the user presses one of the mouse buttons, after which the display is restored to its original state and a BOOL value is returned by this routine to specify whether or not the User pressed the LEFT mouse button.

and this routine returns immediately upon creating the Alert display. The return value is FALSE. If the system cannot recover from this Alert, it's a DEADEND_ALERT

The Alerthumber is a LONG value, related to the value sent to the Alert() routine. But the only bits that are pertinent to this routine are the ALERI_IYPE bits. These bits must be set to either RECOVERY_ALERI for Alerts from which the system may safely recover, or DEADEND_ALERI for those fatal Alerts. These states are described in the paragraph above. There is a third type of Alert, the DAISY_ALERI, which is used only by the Executive.

The AlertMessage The String argument points to an AlertMessage string. The Alert string is comprised of one or more substrings, each of which is comprised of the following components:

describing where on the Alert display you want this string to appear. The y-coordinate describes the offset to the baseline of the text. - first, a 16-bit x-coordinate and an 8-bit y-coordinate,

then, the bytes of the string itself, which must be

continuation byte is non-zero, there IS another substring to be processed in this Alert Message. If the continuation not there's another substring following this one. If the lastly, the continuation byte, which specifies whether or null-terminated (end with a byte of zero)

describes how many video lines tall you want the Alert display to be. The last argument, Height,

byte is zero, this is the last substring in the message.

The only pertinent bits AlertNumber = the number of this Alert Massage. The only pertinent bit of this number are the ALERT_TYPE bits. The rest of the number is ignored by this routine

String = pointer to the Alert message string, as described above Height = minimum display lines required for your message

3 17:04 1985 intuition.doc Page 20 Бес

is always the return value. If this is a RECOVERY MERT. The return value will be TRUE if the User presses the left mouse button in response to your message, and FALSE if the User presses the right hand If this is a DEADEND_ALERT, FALSE button is response to your text. A BOOL value of TRUE or FALSE.

DisplayAlert

If the system is worse off than you think, the level of your Alert may become DEADEND_ALERI without you ever knowing about it.

ModifyIDOM

Modify the state of the Window's IDCMP

SYNOPSIS

;

Mod1fyIDOM

Z

ModifyIDGTP (Window, IDGTPFlags);

FUNCTION

This routine modifies the state of your Window's IDCMP (Intuition Direct Communication Message Port). The state is modified to reflect your desires as described by the flag bits in the value IDCMFFlags. When you call ModifyIDCMP(), if the IDCMFFlags equals NULL, you are asking that if the Port is currently opened, you want it closed. If you set any of the IDCMFFlags, this means that you want the message ports to be open; if not currently opened, the Ports will be opened now.

The four actions that might be taken are: - if there is currently no IDCMP in the given Window, and IDCMPFlags is NULL, nothing happens

if there is currently no IDCMP in the given Window, and any of the IDCMPFlags is selected (set), then the IDCMP of the Window is created, including allocating and initializing the message ports and allocating a Signal bit for your Port. See the "Input and Output Methods" chapter of this book for full details

Intuition to close the Ports, free the buffers and free your Signal bit. You MUST be the same Task that was active if the IDCMP for the given Window is opened, and the IDCMPFlags argument is NULL, this says that you want

argument is not NULL, this means that you want to change the state of which events will be broadcast to you through the IDQMP if the IDOMP for the given Window is opened, and the IDOMPFlags when this Signal bit was allocated

NOTE: You can set up the Window-VüserPort to any Port of your own before you call ModifyIDCMP(). If IDCMFFlags is non-null but your UserPort is already initialized, Intuition will assume that it's a valid Port with Task and Signal data preset and Intuition won't disturb your set up at all, Intuition will just allocate the Intuition Message Port half of it. The converse is true as well: if UserPort is NULL when you call here with IDCMFFlags == NULL, I'll deallocate only the Intuition Port. This allows you to use a Port that you already have allocated:

- OpenWindow() with IDCMFFlags equal to NULL (open no ports)
- set the UserPort variable of your Window to any valid Port of your

own choosing

call ModifyIDCMP with IDCMPFlags set to what you want then, to clean up later, set UserPort equal to NULL before calling CloseWindow() (leave IDCMPFlags alone)

A G-im, Foreboding Note: if you are ever rude enough to close an IDCMP without first having Reply()'d to all of the messages sent to the IDCMP port, Intuition in turn will so rude as to reclaim and deallocate its messages without waiting for your permission.

ONCAGGET (Cadget, Pointer, Requester);
FUNCTION
This command enables the specified Cadget. When a Cadget is enabled, these things happen:
- its imagery is displayed normally (not ghosted)
- the Cadcar Can thereafter be selected by the user
- the Cadget can thereafter be selected by the user
The Pointer argument can point to either a Window or a Screen structure; which it actually points to is decided by examining the SCRANCET flag of the Cadget: if the flag is set, Pointer points to a Screen structure. If the flag is set, Pointer points to a Screen structure. If the Cadget is in a Requester variable can point to a Mindow.

The Requester variable can point to a Window.

NOTE: It's newer safe to tinder with the Cadget list set the Cadget is not the Cadget of a Requester argument may be NULL.

NOTE: If you have specified that this is the Cadget list of a Requester to the Cadget that you want enabled pointer to the Cadget that you want enabled Pointer = pointer to a the Cadget (any be NULL if this isn't a Requester = pointer to a the Cadget (any be NULL if this isn't a Requester Cadget list)

OpenMindow Opens an Intuition window of the given height, width and depth, including already via a call to OpenScreen(). Then Intuition uses your screen argument for the pertinent information needed to get your Window going. On the other hand, if type = one of the Intuition's standard Screens, your screen argument is ignored. Instead, Flags = specifiers for your 'quirements of this window, including:
- which system Cadgets you want attached to your window:
- WINDOWDRAG allows this Window to be dragged
- WINDOWDEPIH lets the user depth-arrange this Window
- WINDOWCLOSE attaches the standard Close Gadget The DetailPen and the BlockPen are used for system rendering; for instance, the Title bar is first filled using the BlockPen, and then the Gadgets and text are rendered using DetailPen. You can either choose to supply special pens for your Window, or, by setting either of these arguments to -1, the Screen's Pens will be used instead. Height = the initial height of this window DetailPen = pen number (or -1) for the rendering of Window details (like gadgets or text in title bar) BlockPen = pen number (or -1) for Window block fills (like Title Bar) the specified system Cadgets as well as any of your own. Allocates Intuition will check to see whether or not that Screen already exists: if it doesn't, it will be opened first before Intuition opens your window in the Standard Screen. If the flag SUPER BITMAP is set, the bitmap variable must point to Left, Top, Width, Height, DetailPen, BlockPen, Flags, IDCMFFlags, Gadgets, CheckMark, Text, Type, Screen, BitMap, MinMidth, MinHeight, MaxWidth, MaxHeight Before you call OperWindow(), you must initialize an instance of a NewWindow structure. NewWindow is a structure that contains all of the arguments needed to open a Window. The NewWindow structure may be discarded immediately after it is used to open If Type == CUSTOMSCREEN, you must have opened your own Screen structure is initialized with the following data: NewWindow = pointer to an instance of a NewWindow structure. where the NewWindow structure is initialized with: Left = the initial x-position for your window Top = the initial y-position for your window Width = the initial width of this window Opens an Intuition Window everything you need to get going. OpenWindow (NewWindow); ; your own BitMap. OpenWindow the Window. OpenWindow SYNOPSIS

BACKDROP for whether or not you want this window to be one See BORDERLESS of Intuition's special backdrop windows.

The mouse move reports (either InputEvents or messages on the IDCMP) that you get will have the x/y coordinates of the After you've opened your Window, if you want to change you can later change the status of this via a call to ReportMouse(). Whether or not your Window is listening to current mouse position, relative to the upper-left corner of your Window (GIMMEZEROZERO notwithstanding). mouse movement events whenever your Window is the active REPORTMOUSE for whether or not you want to "listen" to Mouse is affected by Cadgets too, since they can cause you to start getting reports too if you like. flag can work in conjunction with the IDOMP Flag called MOUSEMOVE, which allows you to listen via the

Dec 3 17:04 1985 intuition.doc Page 48

This is a good way to take over the entire Screen, since you can have a Window cover the entire width of the Screen using Window borders are the only dependable visual division between various Windows and the background Screen. Taking away that Border takes away that visual cue, so make sure this flag. This will work particularly well in conjunction with the BACKOROF flag (see above), since it allows you to open a Window that fills the ENTIRE Screen. NOTE: this is not a flag that you want to set casually, since it may cause visual confusion on the Screen. The that your design doesn't need it at all before you spacing that comes with typical Windows.

would have the effect of yanking the imput rug from under the user). Please use this flag thoughtfully and doing something with another Screen, for instance, your new Window will change where the imput is going, which The active Window is the one that receives imput from the keyboard and mouse. It's usually a good idea to first starts up be an ACTIVATED one, but all others opened later not be ACTIVATED (if the user is off to have the Window you open when your application Window to automatically become the active Window. ACTIVATE is the flag you set if you want this carefully.

and fashioned especially cryptic and unpronounceable to make them squirm with sardonic delight. Here's to you, my chums. Meanwhile, I still opt (and argue) for simplicity and elegance. all hack-heads who love to mangle our brains with maniacal names, RMBIRAP, when set, causes the right mouse button events to be trapped and broadcast as events. You can receive IDCMPFlags = IDCMP is the acronym for Intuition Direct Communications Message Port. It's Intuition's sole acronym, given in honor of these events through either the IDOP or the Console.

a pair of messageports and use them for direct communications with the Task opening this Window (as compared with broadcasting information via the Console Device). See the "Imput and Output If any of the IDOMP Flags is selected, Intuition will create Methods" chapter of this book for complete details.

of that event through the IDCMP rather than via the Console device. You request an IDCMP by setting any of these flags. Except for the special VERIFY flags, every other flag you set This allows a program to interface with Intuition program wants to know about, I'm to broadcast the details directly, rather than going through the Console device. tells me that if a given event occurs which your device.

about a certain set of events (for instance, CLOSEWINDOW); another example would be SIZEVERIFY, which is a function that you get ONLY through the use of the IDCMP (because the Console doesn't give you any way to talk to Intuition directly). for special performance cases; that is, when you aren't going to open a Console for your Window and you do want to learn messages via the Console. Reserve your usage of the IDCMP a Console, it will be far better to get most of the event Remember, if you are going to open both an IDCMP and

Border padding. Your Window may have the Border variables set anyway, depending on what Cadgetry you've requested for the Window, but you won't get the standard border lines and

BORDERLESS should be set if you want a Window with no

Dec 3 17:04 1985 intuition.doc Page 49

zero, no IDCMP is created and the only way you can learn about any Window event for this Window is via a Console opened for this Window. And you have no way to SIZEVERIFY.

If you want to change the state of the IDCMP some time after you've opened the Window (including opening or closing the IDCMP) you call the routine ModifyIDCMP().

The flags you can set are:

it's safe for you to start output again (presuming you're want to make sure that your graphical state is quiescent before something extraordinary happens. In this case, the extraordinary event is that a rectangle of the user is allowed to bring up the DMR equest you've set Set this flag to ask for that verification step. MENUVERIEY (see immediately below), specifies that you graphical data is about to be blasted into your Window. user. Set this flag to ask for that verilleation stay. REQCLEAR is the flag you set to hear about it when the up, and the same for when system has a request for the If you're drawing into that Window, you probably will REQVERIFY is the flag which, like SIZEVERIFY and (see wish to make sure that you've ceased drawing before last Requester is cleared from your Window and using REQVERIEY)

distinct from REQVERIFY. This functions merely tells you that a Requester has opened, whereas REQVERIFY requires and wait for you to finish all graphical output to your Window before rendering the menus. Menus are currently Window which depends on a knowledge of the current size SIZEVERIFY means that you will be doing output to your that User will WAIT until you reply, which suffers the great negative potential of User-Unfriendliness. So you to respond before the Requester is opened. MENUVERIEY is the flag you set to have Intuition stop remember: use this flag sparingly, and, as always with any IDCMP Message you receive, Reply to it promptly! Then, after User has sized the Window, you RECENT is a flag that you set to receive a broadcast when the first Requester is opened in your Window. Compare this with REQCIEAR above. This function is output completes before the sizing takes place (critical Text, for instance). If this is the case, set this flag. Then, when the user wants to size, Intuition will send you the SIZEVERIFY message and Wait() until you reply that it's OK to proceed with Window, you may want to make sure that any queued involves interrupting output to all Windows in the Screen before the Menus are drawn. If you need to the sizing. NOTE: when I say that Intuition will Wait() until you reply, what I'm really saying is finish your graphical output before this happens, rendered in the most memory-efficient way, which of the Window. If the user wants to resize the you can set this flag to make sure that you do.

NEWSIZE is the flag that tells Intuition to send an IDCMP Message to you after the user has resized your Window. At this point, you could examine the size variables can find out about it using NEWSIZE

3 17:04 1985 intuition.doc Page 50

in your Window structure to discover the new size of the Window

whenever your Window needs refreshing. This flag makes sense only with SIMPLE_REFRESH and SWART_REFRESH Windows. REFRESHWINDOW when set will cause a Message to be sent MOUSEBUTTONS will get reports about Mouse-button

Up/Down events broadcast to you (Note: only the the user clicks the Select button over a Gadget, Intuition deals with it and you don't find out ones that don't mean something to Intuition.

flag FOLLOWNOUSE set. Then all mouse movements will be REPORTMOUSE above, or if one of your Gadgets has the MOUSEMOVE will work only if you've set the flag about it through here). recorted here.

you've created with the GADCIMEDIATE flag set, the fact CAUCETDOWN means that when the User "selects" a Cadget will be broadcast through the IDCMP.

GADCETUP means that when the User "releases" a Cadget that you've created with the RELVERIEY flag set, the fact

MENUPICK selects that MenuNumber data will come this way CLOSEWINDOW means broadcast the CLOSEWINDOW event through will be broadcast through the IDCMP.

mouse. Of course, in exchange you lose all of the Console features, most notably the "cooking" of input data and RAWKEY selects that all RAWKEY events are transmitted via open a Console Device to get input from the keyboard and the IDCMP. Note that these are absolutely RAW keycodes, which you will have to massage before using. Setting t and the MOUSE flags effectively eliminates the need to the IDCAP rather than the Console

the systematic output of text to your Window. Gadgets = the pointer to the first of a linked list of the your own Can be NULL Gadgets which you want attached to this Window.

| | Dec 3 17:04 1985 intuition.doc Page 54 |
|---|---|
| | RefreshGadgets |
| | NAME RefreshGadgets Refresh (redraw) the Gadget display |
| | SYNOPSIS RefreshGadgets (Gadgets, Pointer, Requester); |
| | FUNCTION Refreshes (redraws) all of the Cadgets in the Cadget List starting from the specified Cadget. |
| | The Pointer argument can point to either a Window or a Screen structure. Which it actually points to is decided by examining the SCRCADGEI flag in the first Gadget of the list; if the flag is set, then Pointer points to a Screen structure, else it points to a Window structure. |
| | The Requester variable can point to a Requester structure. If the first Cadget in the list has the REQCADCET flag set, the Cadget list refers to Cadgets in a Requester and the Pointer must necessarily point to a Window. If these are not the Cadgets of a Requester, the Requester argument may be NULL. |
| | The two main reasons why you might want to use this routine are: first, that you've modified the imagery of the Cadgets in your display and you want the new imagery to be displayed; secondly, if you think that some graphic operation you just performed trashed the Cadgetry of your display, this routine will refresh the imagery for you. |
| | The Gadgets argument can be a copy of the FirstGadget variable in either the Screen or Window structure that you want refreshed: the effect of this will be that all Gadgets will be redrawn. However, you can selectively refresh just some of the Gadgets by starting the refresh part-way into the list: for instance, redrawing your Window non-GIMWEZEROZERO Gadgets only, which you've conveniently grouped at the end of your Gadget list. |
| · | NOTE: It's never safe to tinker with the Gadget list yourself. Don't supply some Gadget list that Intuition hasn't already processed in the usual way. |
| | NOTE: If you have specified that this is the Gadget list of a Requester, that Requester must be currently displayed |
| | INPUTS Cadgets = pointer to the first in the list of Cadgets wanting refreshment Cadgets = pointer to either a Screen or Window structure (defined by the Pointer = pointer to either first Cadget (see next)) Requester = pointer to a Requester (may by NULL if this isn't a Requester Cadget list) |

| SYNOPSIS Rethindoisplay(); |
| FUNCTION This function performs the Intuition global display reconstruction. This includes: massaging internal state data, rethinking about all of the ViewPorts and their relationship to one another, and, finally, reconstructing the entire display based on the results of all this rethinking. |
| The reconstruction of the display includes calls to the graphics library to perform MrgCop() and LoadView() for all of Intuition's Screens. |
| You may perform a MakeScreen() on your Custom Screen before calling this routine. The results will be incorporated in the new display. |
| WARNING: This routine can take several milliseconds to run, so do not use it lightly. RethinOisplay() does a Forbid() on entry and a Permit() on exit, which can seriously degrade the performance of the multi-tasking Eexecutive. |
| INPUTS None |
| RESULT None |

SetPointer Width = the Width of the sprite (must be less than or equal to sixteen) XOffset = the offset for your sprite from the Pointer position YOffset = the offset for your sprite from the Pointer position of the hardware sprite imagery from what intuition regards as the current position of the Pointer. Another way of describing it is as the offset from the "not spot" of the Pointer to the top-left corner of the sprite. For instance, if you specify offsets of zero, zero, then the top-left corner of your sprite image will be placed at the Pointer position. On the other hand, if you specify an NOffset of 7 (remember, sprites are is pixels wide) then your sprite will be centered over the Pointer position. If you specify an NOffset of -15, the right-edge of the sprite will be over the Pointer position. Window = pointer to the Window to receive this Pointer definition Sets up the Window with the sprite definition for the Pointer. Then whenever the Window is the active one, the Pointer image will change to its version of the Pointer. If the Window is the active one when this routine is called, the change takes place immediately. The XOffset and YOffset are used to offset the top-left corner SetPointer (Window, Pointer, Height, Width, XOffset, YOffset); Pointer = pointer to the data definition of a Sprite Height = the height of the Pointer sets a Window with its own Pointer Dec 3 17:04 1985 intuition.doc Page 65 ClearPointer () SetPointer SetPointer FUNCTION SEE ALSO None RESULT

| SizeWindow | |
| NAME SizeWindow Ask Intuition to size a Window | |
| SYNOPSIS SizeWindow(Window, DeltaX, DeltaX); | |
| FUNCTION This routine sends a request to Intuition asking to size the Window the specified amounts. The delta arguments describe how much to size the Window along the respective axes. | |
| Note that the Window will not be sized immediately, but rather will be sized the next time Intuition receives an input event, which happens currently at a minimum rate of ten times per second, and a maximum of sixty times a second. You can discover when you Window has finally been sized by setting the NEWSIZE flag of the IDCMP of your Window. See the "Input and Output Methods" chapter of this book for description of the IDCMP. | |
| This routine does no error-checking. If your delta values specify some far corner of the Universe, Intuition will attempt to size your Window to the far corners of the Universe. Because of the distortions in the space-time continuum that can result from this, as predicted by special relativity, the result is generally not a pretty sight. | |

WindowLimits

WindowLimits

Set the minimum and maximum limits of the Window

;

WindowLimits

WindowLimits(Window, MinWidth, MinMeight, MaxWidth, MaxMeight);

Sets the minimum and maximum limits of the Window's size. Until this routine is called, the Window's size limits are equal to the Window's initial size, which means that the user won't be able to size it at all. After the call to this routine, the Window will be able to be sized to any dimensions within the specified limits. FUNCTION

If you don't want to change any one of the dimensions, set the limit argument for that dimension to zero. If any of the limit arguments is equal to zero, that argument is ignored and the initial setting of that parameter remains undisturbed

are in range. If any are out of range, the return value from this procedure will be FALSE. If all arguments are valid, the return If any of the arguments is out of range (minimums greater than the current size, maximums less than the current size), that limit will be ignored, though the others will still take effect if they value will be TRUE.

If the user is currently sizing this Window, the new limits will not take effect until after the sizing is completed.

Window = pointer to a Window structure
MinWidth, MinWeight, MaxWeight = the new limits for the size
of this Window. If any of these is set to zero, it will
be ignored and that setting will be unchanged.

RESULT

Returns TRUE if everything was in order. If any of the parameters was out of range (minimums greater than current size, maximums less than current size), FALSE is returned and the errant limit request is not fulfilled (though the valid ones will be).

Appendix B

Device Summaries

This appendix contains Unix-like summaries for the commands that may be applied to ROM (or kickstart) resident devices, as well as summaries of routines in disk-loadable devices.

These documentation files are organized on a device-by-device basis. The tutorial sections of this manual give you information that shows how these device commands relate to each other and the prerequisites for calling them.

To use any of the device commands, you must first open the device. The correct calling sequence for opening each device is shown in the device tutorial chapter itself. This introduction lists the names of the current set of devices that are included with the system.

If the device is disk-resident, it gets loaded and initialized. The OpenDevice() fills in the io_Device and io_Unit fields of your I/O request block, thereby tying that request block to a specific device. When you say DoIO(IORequest), the DoIO() routine, among others, looks in the IORequest to find out which device is to be used. This prevents having to have a complete (duplicate) set of I/O transmit and control functions for each device.

The following is a list of the names of the devices currently a part of the Amiga software. All of these are to be treated as null-terminated strings, given to the **OpenDevice()** function. For example:

error = OpenDevice("keyboard.device",0,IORequest,0);

See the exec.doc summary for OpenDevice() for the meaning of the various fields of this command.

Device Names

audio.device console.device gameport.device keyboard.device parallel.device printer.device serial.device timer.device trackdisk.device

When you have finished using a device, at the end of your program, you should close it, using the CloseDevice() function as follows:

CloseDevice(IORequest);

You must also free whatever memory you may have dedicated to the device communication before your program ends. Note that you must assure that the device has responded to all of your I/O requests by returning your IORequest blocks before you attempt to close the device or deallocate the memory.

If the system is running out of memory and needs to free up space, it can check the accessors field for various devices. If you have closed the device, it decrements its accessors count. For those devices whose accessors value is zero, the system can retrieve the memory that the device had used.

Certain devices have routines associated with them, and can almost be treated as libraries. The devices that have specific interface routines are the timer device and the console device. To access these routines, you must, as with a library, provide a value to a specific Base variable name:

Device Base Address Name

timer TimerBase console ConsoleDevice

To get this base address, you must open the device, then copy the io_Device field from your IORequest block as the base address for this "library" routine. Note that unlike libraries, you need not issue a CloseLibrary() command after using the device routines. The CloseDevice() function call is sufficient.

An example showing how to obtain the base address for the timer device is shown in the "Timer Device" chapter in this manual.

audio.device/BeginIO BeginIO - dispatch a device command Dec 3 17:04 1985 audio.doc Page 3 audio.device/BaginIO

SYNOPSIS BeginIO(10Request);

Begin10 has the responsibility of dispatching all device commands. Immediate commands are always called directly, and all other commands are queued to make them single threaded

10Request -- pointer to the I/O Request for this command

Dec 3 17:04 1985 audio.doc Page

audio.device/BeginIO/ADCAD_ALLOCATE

ADCAD_ALLOCATE -- allocate a set of audio channels

ADCHD_ALLOCATE is a command that allocates multiple audio channels.
ADCHD_ALLOCATE takes an array of possible channel combinations
(loa_Data) and an allocation precedence (ln_Pri) and tries to allocate one of the combinations of channels.

If the channel combination array is zero length (loa_Length), the allocation succeeds; otherwise, ADCMD_ALLOCATE checks each combination, one at a time, in the specified order, to find one combination that does not require ADCMD_ALLOCATE to steal allocated channels. If it must steal allocated channels, it uses the channel combination that steals the lowest precedence channels. ADCHD_ALLOCATE cannot steal a channel of equal or greater precedence than the allocation precedence (ln.Pri). If it fails to allocate any channel combination and the no-wait flag (ADIOE_NOWALT) is set ADCHD_ALLOCATE returns a zero in the unit field of the I/O request (io_Unit) and an error (IOERR_ALLOCEALLED). If the no-wait flag is clear, it places the I/O request in a list that tries to allocate again whenever ADCHD_FREE frees channels or ADCHD_SETRREC lowers the channels' precedences.

are locked (ADCMD_LOCK) and if so, replies (ReplyMsg) the lock I/O request with an error (ADIOERR_CHANNELSTOLEN). Then it places the allocation I/O request in a list waiting for the locked channels to be freed. When all the allocated channels are un-locked, ADCMD_ALLOCATE: resets (CMD_RESET) the allocated channels, generates a new allocation key (loc_Allockey), if it is zero, copies the allocation key into each of the allocated channels If the allocation is successful, ADOMO_ALLOCATE checks if any channels

copies the allocation precedence into each of the allocated channels, and

copies the channel bit map into the unit field of the I/O request.

If channels are allocated with a non-zero allocation key, ADCMD_ALLOCATE allocates with that same key; otherwise, it generates a new and unique key.

ADCAD_ALLOCATE is synchronous:

. if the allocation succeeds and there are no locked channels to be stolen, or

. If the allocation fails and the no-wait flag is set.

. If the allocation fails and the no-wait flag is set.
In either case, ADCMD_ALLOCATE only replies (mr_ReplyPort) if the quick flag (IOF_QUICK) is clear; otherwise, the allocation is asynchronous, so it clears the quick flag and replies the I/O request after the allocation is finished. If channels are stolen, all audio

pointer to channel combination options (byte array, bits 0 thru 3 correspond to channels 0 thru 3)
- length of the channel combination option array (0 thru 16, 0 always succeeds) If you decide to store directly to the audio hardware registers, you must either lock the channels you've allocated, or set the precedence to maximum (ADALLOC_MANDREC) to prevent the channels from being device commands return an error (IOERR_NOALLOCATION) when the former user tries to use them again. Do not use ADCHD_ALLOCATE in interrupt pointer to message port that receives I/O request after ADIOF_NOWALT- (CLEAR) if allocation fails, wait till is bit map of successfully allocated channels (bits 0 thru 3 correspond to channels 0 thru 3)

ADCHO_FINISH -- abort writes in progress to audio charmels Dec 3 17:04 1985 audio.doc Page audio.device/BeginIO/ADCAD_FINISH

audio.device/BeginIO/ADCMD_FINISH

FUNCTION

SOURCE INISH is a command for multiple audio channels. For each selected channel (io_Unit), if the allocation key (loa_AllocKey) is correct and there is a write (DED_WRITE) in progress, ADCHD_FINISH aborts the current write immediately or at the end of the current cycle depending on the sync flag (ADIOE_SYNCYCLE). If the allocation key is incorrect ADCHD_FINISH returns an error (ADIOERR_NOALLOCATION). ADCHD_FINISH is synchronous and only replies (mr_ReplyPort) if the quick flag (IOE_QUICK) is clear. Do not use ADCHD_FINISH in interrupt code at interrupt level 5 or higher.

INPUTS

bit map of channels to finish (bits 0 thru 3 correspond - pointer to device node, must be set by (or copied from (SET) finish at the end of current m_ReplyPort- pointer to message port that receives I/O request (CLEAR) reply I/O request (CLEAR) finish immediately if the quick flag (iOF_QUICK) is clear I/O block set by) OpenDevice function flags, must be cleared if not used: command number for ADCMD_FINISH to channels 0 thru 3) IOE_QUICK -ADIOE_SYNCCYCLEto_Command to Device to Flags 10_Unit

ioa_AllocKey- allocation key, must be set by (or copied from I/O block set by) OpenDevice function or ADC#D_ALLOCATE command

OUTPUTS

bit map of channels successfully finished (bits 0 thru 3 correspond to channels 0 thru 3) error number: 10 Error 10_Unit

ADIOERR_NOALLOCATION - allocation key (loa_Allockey)
does not match key for channel

Dec 3 17:04 1985 audio.doc Page 7

audio.device/BeginIO/ADCAD_FREE

iudio.device/BeginIO/ADCAD_FREE

ADOMD_FREE -- free audio channels for allocation

FUNCTION

ADCED_FREE is a command for multiple audio charmels. For each selected channel (io_Unit), if the allocation key (ioa_AllocKey) is correct, ADCE_FREE does the following:
restores the channel to a known state (OM_RESET),

changes the channels allocation key, and makes the channel available for re-allocation.

If the channel is locked (ADCHD_LOCK) ADCHD_FREE unlocks it and clears the bit for the channel (10_Unit) in the lock I/O request.

If the lock I/O request has no channel bits set ADCHD_FREE replies the lock I/O request, and

checks if there are allocation requests (ADCMD_ALLOCATE) waiting for the channel. Otherwise, ADCHD_FREE returns an error (ADIOERR_NOALLOCATION).
ADCHD_FREE is synchronous and only replies (mn_ReplyPort) if the quick flag (IOF_QUICK) is clear. Do not use ADCHD_FREE in interrupt code.

INPUTS

m. ReplyPort- pointer to message port that receives I/O request if the quick flag (IOE_QUICK) is clear

- pointer to device node, must be set by (or copied from I/O block set by) OpenDevice function to Device

- bit map of charmels to free (bits 0 thru 3 correspond to lo_Unit

- command number for ADCMD FREE channels 0 thru 3) lo Command

- flags, must be cleared if not used: to Flags

IOF_QUICK - (CLEAR) reply I/O request allocation key, must be set by (or copied from I/O block set by) OpenDevice function or ADCMD_ALLOCATE command ion Allockey-

bit map of channels successfully freed (bits 0 thru 3 correspond to channels 0 thru 3) io_Unit

error number: to Error

does not match key for channel ADIOERR_NOWLLOCATION - allocation key (loa_AllocKey) - no error

Dec 3 17:04 1985 audio.doc Page 8

audio.device/BeginIO/ADCMD_LOCK

audio.device/BeginIO/ADCHD_LOCK

ADCHD_LOCK -- prevent audio channels from being stolen

ADCMD_LOCK is a command for multiple audio channels.

For each

allocations (ADCMD_ALLOCATE or OpenDevice) from stealing the channel. Otherwise, ADCMD_LOCK returns an error (ADIOERR_NOALLOCATION) and will selected channel (lo_Unit), if the allocation key (loa_AllocKey) is correct, ADCM_LOCK locks the channel, preventing subsequent not lock any channels.

Unlike setting the precedence (ADCMD_SETPREC, ADCMD_ALLOCATE or OpenDevice) to maximum (ADALLOC_MAXCREC) which would cause all subsequent allocations to fail, ADCMD_LOCK causes all higher precedence allocations, even no-vait (ADIOE_NOWAIT) allocations, to wait until the channels are un-locked.

Locked channels can only be unlocked by freeing them (ADCMD_FREE), which clears the channel select bits (io_Unit). ADCMD_LOCK does not reply the I/O request (mn_ReplyPort) until all the channels it locks are freed, unless a higher precedence allocation attempts to steal one the locked channels. If a steal occurs, ADCMD_LOCK replies and returns an error (ADIOERR_CHANNELSTOLEN). If the lock is replied (mn_ReplyPort) with this error, the channels should be freed as soon as possible. To avoid a possible deadlock, never make the freeing of stolen channels dependent on another allocations completion.

5 which case it clears the quick flag (IOE_QUICK); otherwise, it is synchronous and only replies if the quick flag (IOE_QUICK) is clear. Do not use ADCHD_LOCK in interrupt code. ADCMD_LOCK is only asynchronous if the allocation key is correct,

· INPUTS

mn_ReplyPort- pointer to message port that receives I/O request if the quick flag (IOE_QUICK) is clear to device node, must be set by (or copied from

- bit map of channels to lock (bits 0 thru 3 correspond to I/O block set by) OpenDevice function 10_Unit

channels 0 thru 3)

Dec 3 17:04 1985 audio.doc Page 20

audio.device/CloseDevice FUNCTION

The CloseDevice routine notifies the audio device that it will no longer be used. It takes an I/O audio request block (IOWudio) and clears the device pointer (io_Device). If there are any channels allocated with the same allocation key (loa_Allockey), CloseDevice frees (ADCMD_FREE) them. CloseDevice decrements the open count, and if it falls to zero and an expunge (Expunge) is pending, the device is st - pointer to audio request block (struct IOAudio)
lo_Device - pointer to device node, must be set by (or
copied from I/O block set by) open (openDevice)
io_Unit - bit map of channels to free (ADCM_FREE) (bits 0
thru 3 correspond to channels 0 thru 3)
ioa_Allockey- allocation key, used to free channels iORequest - pointer to audio request block (struct IOAudio)
io_Device - set to -1
io_Unit - set to zero CloseDevice - terminate access to the audio device Dec 3 17:04 1985 audio.doc Page 22 CloseDevice (iORequest); audio.device/CloseDevice INPUTS 10Request expunded. SYNOPSIS OUTPUTS If CMD_MRITE starts the write immediately after stopping a previous write, you must set the ADIOE_PERVOL flag or else the new data pointer (low_Data) and length (low_Length) may not be loaded. ADIOERR_NOALLOCATION - allocation key (loa_AllocKey) does not match key for charmel - canceled (AbortiO) or charmel - no error stolen Dec 3 17:04 1985 audio.doc Page 21 IOERR ABORTED

audio.device/OpenDevice It takes an allocation key (loa Allockey); otherwise, it returns an error (IOERR_OPENEALL). OpenDevice increments the open count keeping the device from being expunged (Expunge). If the length (loa_Length) is non-zero, OpenDevice tries to allocate (ADCM_ALLOCATE) audio channels from a array of channel combination options (loa_Data). If the array, bits 0 thru 3 correspond to channels 0 thru 3), only necessary for allocation (non-zero allocation succeeds, the allocated channel combination is loaded into the unit field (loa_Unit); otherwise, Openbevice returns an error ADIOERRALICETAILED). Openbevice does not wait for allocation to succeed and closes (CloseDevice) the audio device if it fails. To allocate channels, Openbevice also requires a properly initialized reply port (m_ReplyPort) with an allocated signal bit. - bit map of successfully allocated channels (bits IOERR_OPENFAIL - open failed ADIOERR_ALLOCFAILED - allocation failed, no open loa_AllocKey- unique allocation key, if OpenDevice succeeds The OpenDevice routine grants access to the audio device. It takes I/O audio request block (iORequest) and if it can successfully open the audio device, it loads the device pointer (io_Device) and the length)
- length of the channel combination option array pointer to device node if OpenDevice succeeds, mn_ReplyPort- pointer to message port for allocation, only - pointer to channel combination options (byte 0 thru 3 correspond to channels 0 thru 3) if allocation, otherwise 0 error = OpenDevice("audio.device", unitNumber, 10Request, flags); - allocation precedence (-128 thru 127), only necessary for allocation (non-zero length) necessary for allocation (non-zero length) 10Request - pointer to audio request block (struct IOAudio) iORequest - pointer to audio request block (struct IOAudio) (0 thru 16), zero for no allocation - no error OpenDevice - open the audio device - error number: otherwise -1 3 17:04 1985 audio.doc Page 24 - copy of 10 Error unitNumber- not used - not used loa Length audio.device/OpenDevice to Device loa Data ויקטו to Error SYNOPSIS flags FUNCTION error OUTPUTS audio.device/Expunge The Expunge routine is called when a user issues a RemDevice call. By the time it is called, the device has already been removed from the device list, so no new opens will succeed. The existence of any other users of the device, as determined by the device open count being non-zero, will cause the Expunge to be deferred. When the device is not in use, or no longer in use, the Expunge is actually performed.

EXPUNCE - indicate a desire to remove the Audio device

This function is different from standard device commands in that it is a function in the console device library vectors. The "OpenLibrary" call for the console device is to OpenDevice("console device", -1, 10Request, 0), and then grab the io_Device field out of the iORequest as the library vector.

Accept input events from the producer, which is usually the rom imput.task.

| NAME OpenDevice - a request to open a Console device | SINCESIS OpenDevice ("console.device", unit, iORequest, 0) FUNCTION The open routine grants access to a device. There are two fields in the iORequest block that will be filled in: the IO_DEVICE field and possibly the IO_UNIT field. | This open command differs from most other device open commands in that it requires some information to be supplied in the IO_DATA field of the iORequest block. This initialization information supplies the window that is used by the console device for output. | The unit number that is a standard parameter for an open call is used specially by this device. A unit of -1 indicates that no actual console is to be opered, and is used to get a pointer to the device library vector. A unit of zero binds the supplied window to a unique console. Sharing a console must be done at a level higher than the device. There are no other valid unit numbers. | 10 REQUEST io_Data This is the window that will be used for this console. It must be supplied if the unit in the OpenDevice call is 0 (see above). The RPort of this window is potentially in use by the console whenever there is an outstanding write command. | | |

console.device/RawKeyConvert

console.device/RawKeyConvert

SYNOPSIS

actual = RawKeyConvert(event, buffer, length, keyMap),

RawKeyConvert - decode raw input classes

consoleDev

8

2 ដ Z 8

FUNCTION

8

This console function converts input events of type IECLASS_RAWREY to ANSI bytes, based on the keyMap, and places the result into the buffer.

INPUTS

length - maximum anticipation, 1.e. the buffer size in bytes. keyMap - a KeyMap structure pointer, or null if the default console device key map is to be used. event - an InputEvent structure pointer.
buffer - a byte buffer large enough to hold all anticipated
characters generated by this conversion.

RESULTS

actual - the number of characters in the buffer, or -1 if a buffer overflow was about to occur.

if actual is -1, a buffer overflow condition was detected. Not all of the characters in the buffer are valid.

that it is a function in the console device library vectors. The "OpenLibrary" call for the console device is to OpenDevice ("console.device", -1, 10Request, 0), and then grab the io Device field out of the 10Request as the library This function is different from standard device commands in

console.device/Read

console.device/Read

S S

Read - return the next input from the keyboard

FUNCTION

Read the next input, generally from the keyboard. The form of this input is as an ANSI byte stream: i.e. either ASCII text or control sequences. Raw input events received by the console device can be selectively filtered via the SRE and RRE control sequences (see the write command). Keys are converted via the keymap associated with the unit, which is modified with AskKeyMap and SetKeyMap

<CSI>1;0;<keycode>;<qualifiers>;0;0;<seconds>;<microseconds>q would return raw keycode reports with the information from If, for example, raw keycodes had been enabled by writing $\langle CSI>1s$ to the console (where $\langle CSI>1s$ \$98 or Esc[), keys the input event itself, in the form:

satisfied, but if there is some input, but not as much as can fill IO_LENCIH, the request will be satisfied with the input If there is no pending input, this command will not be currently available.

IO REQUEST

mn.ReplyPort set if quick I/O is not possible preset by the call to OpenDevice preset by the call to OpenDevice IOF_QUICK if quick I/O possible, else zero The destination for the characters to read from the keyboard. sizeof(*buffer) char buffer[] CO READ io_Message to_Device to_Command to_Flags to_Length to_Unit o Data

RESULTS

and fills This function sets the error field in the iORequest, and fillithe iORequest IO_DATA area with the next input, and IO_ACTUAL with the number of bytes read.

narrator.device/Open of these operations fail, an error is returned (see the .hi files for possible error return codes). Next, OpenDevice (done for all opens, not just the first one) initializes the user's IORequest block (IORB). Default values for sex, rate. to use non-default values for these parms, the values must be set after the open is done. OpenDevice then assigns a pseudo-unit number to the IORB for use in synchronizing read and write requests. See the read command for more details. OpenDevice checks the unit number, and if non-zero, returns an error (ND UnitErr). If this is the first time the driver has been opened, OpenDevice will attempt to open the audio device and allocate the driver's static buffers. If either pitch, pitch mode, sampling frequency, and mouths are set in the appropriate fields of the IORB. Note that if users wish The OpenDevice routine grants access to the narrator device. Finally, OpenDavice stores the davice node pointer in the IORB and clears the delayed expunge bit. error = OpenDevie("narrator.device", 0, IORequest, 0); - the user's ICRB (need not be initialized) error - same as to Error field of IORB deviceName - must be "narrator.device" OpenDevice - open the narrator device. INPUTS

!ORequest -- pointer to an I/O Request Block of size
!o_ExtParSize (see paralle).! for size/definition),
containing a valid function in lo_Command to process,
as well as the function's other required parameters.
devicaNode -- pointer to the "paralle].device" node built at
init, and put into lo_Device at Open.

Error -- if the BeginIO succeded, then Error will be null. If the BeginIO failed, then the Error will be non-zero. Most I/O errors won't be reported until the ReplyMsg.

This function initiates a I/O request made to the parallel device. Other than read or write, the functions are performed synchronously, and do not depend on any interrupt handling logic (or it's associated discontinuities), and hence, if so selected, can be performed as IC_QUICK.

Reads and writes are merely initiated by BeginlO, and thusly return to the caller as begun, not completed. Completion is signalled via the standard ReplyMsg routine. A valid read or write request is performed asynchronously, and never as IC_QUICK. Multiple requests are handled via FIEO queueing.

BeginIO -- start up an I/O process

NAME
OpenDevice - a request to open a Console device
SYNOPSIS
OpenDevice ("console.device", unit, 10Request, 0)
FUNCTION
The open routine grants access to a device. There are two fields in the 10Request block that will be filled in: the IO_DEVICE field and possibly the IO_UNIT field.
This open command differs from most other device open commands in that it requires some information to be supplied in the IO_DATA field of the 10Request block. This initialization information supplies the window that is used by the console device for output.

Dec 3 17:04 1985 rawinput.doc Page 6

The unit number that is a standard parameter for an open call is used specially by this device. A unit of -1 indicates that no actual console is to be opened, and is used to get a pointer to the device library vector. A unit of zero binds the supplied window to a unique console. Sharing a console must be done at a level higher than the device. There are no other valid unit numbers.

IO REQUEST

io_Data

This is the window that will be used for this console. It must be supplied if the unit in the Openbevice call is 0 (see above). The RPORT of this window is potentially in use by the console whenever there is an outstanding

write command.

Dec 3 17:04 1985 rawlmput.doc Page 7

console.device/RawKeyConvert

NAME
RawKeyConvert - decode raw imput classes

SYNOPSIS

Dec 3 17:04 1985 rawimput.doc Page

actual = RawKeyConvert (event, buffer, length, keyMap),
consoleDev A0 A1 D1 A2
A6 A6

This console function converts input events of type IECLASS_RAWKEY to ANSI bytes, based on the keyMap, and places the result into the buffer.

places the result into the buffer.

INPUTS

event - an ImputEvent structure pointer.

buffer - a byte buffer large enough to hold all anticipated characters generated by this conversion.

length - maximum anticipation, i.e. the buffer size in bytes. keyMap - a KeyMap structure pointer, or null if the default consoled device by map is to be used.

consoleder - the lo_Device of the console device.

RESULIS actual - the number of characters in the buffer, or -1 if a buffer overflow was about to occur.

ERRORS

if actual is -1, a buffer overflow condition was detected.

Not all of the characters in the buffer are valid.

NOTES

This function is different from standard device commands in that it is a function in the console device library vectors.

The "OpenLibrary" call for the console device is to OpenDevice ("console device", -1, iORequest, 0), and then grab the io_Device field out of the iORequest as the library

console.device/Read Read the next input, generally from the keyboard. The form of this input is as an ANSI byte stream: i.e. either ASCII text or control sequences. Raw input events received by the console device can be selectively filtered via the SRE and RRE control sequences (see the write command). Keys are converted via the keymap associated with the unit, which is modified with AskKeyMap and SetKeyMap <CSI>1;0; <keycode>; <qualiflers>;0;0; <seconds>; <mlcroseconds>q satisfied, but if there is some input, but not as much as can fill IO_LENCTH, the request will be satisfied with the input mn_ReplyPort set if quick I/O is not possible preset by the call to OpenDevice preset by the call to OpenDevice would return raw keycode reports with the information from the input event itself, in the form: IOF_QUICK if quick I/O possible, else zero The destination for the characters to read If, for example, raw keycodes had been enabled by writing <CSI>1s to the console (where <CSI> is \$98 or Esc[), keys If there is no pending input, this command will not be Read - return the next input from the keyboard from the keyboard. sizeof (*buffer) char buffer[] CAD READ currently available. console.device/Read 10 Message to_Command 10_Length 10_Data 10 Device to Flags 10_Unit IO REQUEST

console.device/Write INDEX: move the active position down one line m.ReplyPort set if quick I/O is not possible preset by the call to OpenDevice preset by the call to OpenDevice OND_WRITE IOF_QUICK if quick I/O possible, else zero sizeof(*buffer), or -1 if mull terminated char buffer[] a buffer containing the ANSI text to write to Control Sequences (introduced by CSI, 1.e. \$9B or Esc[) with parameters: "1" is an optional numeric parameter. "2" are two numeric parameters - e.g. '14;94', and "3" is any number of numeric parameters, seperated by semicolins --Write a text record to the display. Note that the RPort of the console window is in use while this write command is pending. CONTROL SEQUENCE INTRODUCER: see next list ISO Compatable Escape Sequences (introduced by Esc) Independent Control Functions (no introducer) HORIZONTAL TABULATION SET the console device. serial.device/BeginIO

FUNCTION

device. Other than read or write, the functions are performed synchronously, and do not depend on any interrupt handling logic (or it's associated discontinuities), and hence, if so selected, can be performed as IO_QUICK. This function initiates a I/O request made to the serial BeginIO -- start up an I/O process

With one exception, reads and writes are merely initiated by Beginlo, and thusly return to the caller as begun, not completed. Completion is signalled via the standard ReplyMsg routine. Multiple requests are handled via FIFO queueing. The only exception to this non-QUICK handling of reads and writes

- IO_QUICK bit is set is for READS when:

There are no pending read requests

- There is already enough data in the input buffer to satisfy this I/O Request immediately.

In this case, the IO_QUICK flag is not cleared, and the request is completed by the time it returns to the caller. There is no ReplyMsg or signal bit activity in this case.

INPUTS

as well as the command's other required parameters.

deviceNode -- pointer to the "serial.device" node built at 1ORequest -- pointer to an I/O Request Block of size 1o_ExtSerSize (see serial.1 for size/definition), containing a valid command in 1o_Command to process, init, and put into io_Device at Open.

RESULTS

Error. -- if the BeginIO succeded, then Error will be null.

If the BeginIO failed, then the Error will be non-zero.

Most I/O errors won't be reported until the ReplyMsg.

Dec 3 17:04 1985 serial.doc Page 4

serial.device/Break

serial.device/BeginIO

serial.device/Break

Break -- send a break signal over the serial line

for an extended period) out the serial port. This is accomplished by setting the UNYTERK bit of reg ADKCON. After a duration (user specifiable via setparams, default 25000 microseconds) the bit is reset and the signal discontinued. If the QUEUEDERK bit of 10_SerFlags is set in the 10_Request block, the request is placed at the back of the write-request queue and executed in turn. If the QUEUEDERK bit is not set, the break is started immediately, control returns to the caller, and the timer discontinues the signal after the duration is completed. It is up to the caller to co-ordinate his/her intentions with the proper commands such as ABCRT, FLUSH, STOP, START, etc... This function sends a break signal (serial line held low

Sorial.device/Open

NAME

Open -- a request to open the serial port

SYNOPSIS

OpenDevice (sername, unit, loRequest, flags)

FUNCTION

This function allows the requestor software access to the serial device. Unless the shared-access bit (bit 5 of 10_SerTelags) is set, exclusive use is granted and no other access is allowed until the owner closes the device. All serial-specific fields are initialized to their most recent values (or default, if the first time open). OpenDevice initializes the io_Device and lo_Unit fields to 0, since there is only one serial device/unit. If the user wants to support 7-wire handshaking (i.e. RS332-C CIS/RTS protocol), he should set the 7MRE bit before opening.

INPUTS

Sername - pointer to literal string "serial.device"

Lignored

LoRequest - Deinter to an loRequest block of size lo_ExtSerSize

(see serial.i.h for size/definition) to be initialized by the OpenDevice routine.

MOTE use of lo_SerFlags (see FUNCTION above)

#@CX! INPORTANT !!! LoRequest block MUST (!!) be of size lo_ExtSerSize !!!

NAME

Read -- read input from serial port

FUNCTION

This function causes a stream of characters to be read in the serial port. The number of characters is specified in io_Length, unless -1 is used, in which case input is read until an mull(0x00) is received. Input for which there is no request is stored in the input buffer until it can be dispatched to a requestor.

serial.doc Page 10

serial.device/Reset This function resets the serial port to its freshly initialized condition. It aborts all I/O requests both queued and current, relinquishes the current buffer, obtains a new default sized buffer, and sets the port's flags and parameters to their boot-up time default values. The functions places the reset If the Reset failed, then the Error will be non-zero. Error -- if the Reset succeded, then Error will be null. mn.ReplyPort initialized set by OpenDevice set by OpenDevice CMD_RESET parameter values in the lokequest block. Reset -- reinitializes the serial port Dec 3 17:04 1985 serial.doc Page 11 serial.device/Reset 10 Message 10 Command 10 Device io_Unit IO REQUEST RESULTS

serial.device/SetParams checks for parity, x-OFF handling, character lengths other than 8 bits, and testing for a break signal. Setting RAD_BOCGIE will also set the XDISABLED bit.

Note that writing data (that's already in MIDI format) at MIDI rates is easily accomplished. Using this driver alone for MIDI reads may, however, be inappropriate, due to MIDI timestamping requirements, to reflect the serial device's current configuration. If trying to run MIDI, it is suggested to set the RAD_BOCCIE bit of io_SerFlags to bypass unneeded overhead. Specifically, this skips Valid input for io_Baud is between 112 and 292000 baud inclusive; and possibility of overruns in a busy multitasking and/or display - that the following fields are filled in by Open The ECFNODE and QUEUEDERK bits of io_SerFlags can be set/reset RBuffen must be at least 512.

lo_ExtFlags is not used in VI.1, and MUST be set to zero to assure upward compatibility.

xON-xOFF is by default enabled. The XDISABLED bit is the only parameter that can be changed via a SetParams call while the device is active. Note that this vill return the value serErr_DevBusy in the lo_Error field. asynchronous 1/o above 32KB (especially on a busy system) may This function allows the caller to change parameters for the serial device. Except for xON-xOFF enable/disable, it will reject a setparams call if any reads or writes are active in the lo_Rqst block without a call to SetParams. The SHARED and 7WIRE bits of lo_SerFlags are used in OpenDevice calls. ALL OTHER PARAMETERS CAN OWLY BE CHANGED BY THE SetParams that any change in buffer size causes the current buffer to be deallocated and a new, correctly sized one to be allocated. Thusly, the CONTENIS OF THE OLD BUFFER ARE LOST. baud rate for reads AND writes. (See 1 above) a longword containing byte values for the xON, xOFF, INQ, ACK fields (respectively) (INQ/ACK not used at this time) SetParams -- change parameters for the serial port length in bytes of input buffer mn_ReplyPort initialized SDCMD_SETPARAMS (0x0B) set by OpenDevice set by OpenDevice (not used) intensive environment. translator.library/Close translator.library/Open translator.library/Translate

TABLE OF CONTENTS

translator.library/Open The open routine grants access to the translator library and returns the library node. The name "TranslatorPase" must be used and it must be declared to be external and long. OpenLibrary - Grants access to the translator library libNode - This must be called "TranslatorBase" and libNode = OpenLibrary ("translator.library", 0); library name - "translator.library" Dec 4 09:14 1985 translator.doc Page 3 declared as extern long. translator.library/Open version SYNOPSIS FUNCTION SEE ALSO RESULTS INPUTS

Dec 4 09:14 1985 translator.doc Page 4

translator.library/Translate

NAME:

translator.library/Translate

Translate - Converts an English string into phonetics

SYNOPSIS rtnCode = Translate(instring, inlen, outbuf, outlen)

FUNCTION

The translate function converts an English string into a string of phonetic codes suitable as imput to the narrator device.

INPUTS

instring - pointer to English string inlen - length of English string outbuf - a char array which will hold the phonetic codes outlen - the length of the output array

RESULTS

Translate will return a zero if no error has occured. The only error that can occur is overflowing the output buffer. If Translate determines that an overflow will occur, it will stop the translation at a word boundary before the overflow happens. If this occurs, Translate will return a negative number whose absolute value indicates where in the INPUT string Translate stopped. The user can then use the offset -rtnCode from the beginning of the buffer in a subsequent Translate call to continue the translation where s/he left off.

Resource Summaries

Resources are software entities in the Amiga Kernel software that enable cooperating tasks to gain exclusive access to certain parts of the Amiga hardware.

There are four resources in the Amiga system:

disk allows access to one of four possible disk units.

cia allows you to access specific bits in each of the Complex Interface Adaptors.

potgo manages the bits of the POTGO register.

misc manages the serial and parallel port register bits.

Each routine for resource management is outlined in the summary sections that follow.

NOTE: Resources need only be used if a user is attempting to use the associated hardware directly. The system software routines utilize these resources internally when they perform hardware operations. Tasks that also utilize these software resource controls will be compatible with Exec and the system software.

To utilize the routines listed for the resources, as with libraries, you must first open the resource and assign the value returned to a specific base pointer name. Here is a list of the resource names and their associated base pointer names. As with libraries, the name is a null-terminated string:

Resource Name Base Pointer Name

potgo.resource

PotgoBase

disk.resource -

none provided, for asm language

programmers only

none provided, for asm language

programmers only

ciaa.resource

misc.resource

<user-defined> <user-defined>

Examples:

struct Library *PotgoBase;
PotgoBase = (struct Library *)OpenResource("potgo.resource");
/* then use the routines provided */
....

/* <user-defined > example */
struct Library *myCiaPointerA;

myCiaPointerA = (struct Library *)OpenResource("ciaa.resource");

/* then utilize myCiaPointerA as one of the explicit parameters

* for the C language calls to the resource routines. */

cia.resource/AbleiCR resource - pointer to claa.resource or clab.resource as obtained from the call to OpenResource This function provides a means of enabling and disabiling 8520 CIA interrupt control registers. In addition it returns the previous enable mask. oldMask - the previous enable mask before the requested changes. To get the current mask without making changes, call the function with a null parameter. Enabling the mask for a pending interrupt will cause an immediate processor interrupt (that is if everything else is enabled). You may want to clear the pending mask - a bit mask indicating which interrupts to be modified. If bit 7 is clear the mask indicates interrupts to be disabled. If bit 7 is set, the mask indicates interrupts to be enabled. Bit positions are identical to those in 8520 ICR. interrupts with SetICRx prior to enabling them. disk.resource/FreeUnit

NAME
FreeUnit - deallocate the disk

SYNOPSIS
FreeUnit(unitNum), DRResource
DO A6

FUNCTION
This routine deallocates one of the units of the disk. It should be called when done with the disk. Do not call it if you did no successfully allocate the disk (there is no protection -- you will probably crash the disk system).

INPUTS

will probably crash the disk system).

RESULTS

EXCEPTIONS

disk.resource/CetUnit

lastDriver = GetUnit(unitPointer), DRResource

SYNOPSIS

FUNCTION

CetUnit - allocate the disk for a driver

Dec 4 09:12 1985 dlsk.doc Page 4

disk.resource/CetUnit

This routine allocates the disk to a driver. It is either immediately available, or the request is saved until the disk is available. When it is available, your unitPointer is sent back to you (via ReplyMsg). You may then reattempt the GetUnit.

Allocating the disk allows you to use the disk's resources. Remember however that there are four units to the disk; you are only one of them. Please be polite to the other units (by never selecting them, and by not leaving interrupts enabled, etc.).

When you are done, please leave the disk in the following state: dmacon dma bit ON disk long want entenaidsk sync and disk block interrupts -- Both DISABLED CIA resource index interrupt -- DISABLED CIA resource index interrupt -- DISABLED 8520 outputs -- doesn't matter, because all bits will be set to inactive by the resource.

INPUTS

unitPtr - a pointer you your disk resource unit structure.
Note that the message filed of the structure MUST
be a valid message, ready to be replied to.
RESULTS

lastDriver - if the disk is not busy, then the last unit
to use the disk is returned. This may be used to
see if a driver needs to reset device registers.
(If you were the last user, then no one has changed
any of the registers. If someone else has used it,
then any allowable changes may have been made). If the
disk is busy, then a null is returned.

Appendix D

C Include Files—".h" Files

This appendix contains the C-language include files that define the system data structures used by the ROM (or kickstart) routines and the disk-loadable libraries.

As with the documentation files, these include-files are organized on a functional basis. In other words, things pertinent to the exec are listed under "exec/something.h", things pertinent to graphics are listed under "graphics/graphicsitem.h" and so on.

This appendix is a hard-copy of the "SYS:includes" directory on the Amiga C (Lattice C) disk.

 /* the PlanePick and PlaneOnOff variables work much the same way as the
 If that bit is clear, a "plane" of zeroes will be used. If the bit is set, ones will go out instead. So, for our example: Gadget.PlanePick = 0x02;
 for every plane of the RastPort, you need define data only for the planes that are not entirely zero or one. As you define your Imagery, you will often find that most of the planes ARE just as color selectors. For instance, if you're designing
 will reside in a five-plane display, bit plane zero of your imagery would be all ones, bit plane one would have data that describes the imagery, and bit planes two through four would be all zeroes. Using these flags allows you to avoid wasting all that memory in this way: first, you specify which planes you want your data to appear in using the PlanePick variable. For each bit set in the variable, the next "plane" of your image
 mechanism for image data. Rather than defining the image data
 a two-color Gadget to use colors two and three, and the Gadget
 data is blitted to the display. For each bit clear in this variable, the corresponding bit in PlaneOnOff is examined. If that bit is clear, a "plane" of zeroes will be used.
 Gadgat.PlaneOnOff = 0x01;
Gadgat.PlaneOnOff = 0x01;
Note that this also allows for generic Gadgats, like the System Gadgats, which will work in any number of bit planes. Note also that if you want an Image that is only a filled rectangle, you can get this by setting PlanePick to zero
This is a brief image structure for very simple transfers of
 equivalent GELS Bob variables. It's a space-saving
 image data to a RastPort

## Appendix E

# Assembly Include Files—".i" Files

This appendix contains the assembly language include files that define the system data structures used by the ROM (or kickstart) routines and the disk-loadable libraries.

As with the documentation files, these include-files are organized on a functional basis. In other words, things pertinent to the exec are listed under "exec/something.i", things pertinent to graphics are listed under "graphics/graphicsitem.i" and so on.

This appendix is a hard-copy of the "SYS:includes" directory on the Amiga Macro Assembler disk.

 These commands
 TD_NAME is a generic macro to get the name of the driver. This
 --- way if the name is ever changed you will pick up the change
 number of disk changes
number of disk changes
is there a disk in the drive?
is the disk write protected?
 control the disk's motor explicit seek (for testing)
 ; removal/insertion count
; sector label data region
 * extended 10 has a larger than normal to request block.
 * The disk driver has an "extended command" facility.
* take a superset of the normal IO Request block.
 format disk
 * labels are TD_LABELSIZE bytes per sector
